# Sharing

$$\Delta = \lambda x.(x x), F = \lambda x.(x y), I = \lambda x.x$$

## Copies and families

COPY

FAMILY

The problem: share the reduction of redexes in a same family.

## Copies and families

The problem: share the reduction of redexes in a same family.

## Call by need is not optimal

We need to reduce under lambdas:

$$\mathbf{n} = \lambda xy.(x (x \dots (x y)))$$

$$\mathbf{2} = \lambda xy.(x (x y))$$

$$\mathbf{I} = \lambda x.x$$

$$\begin{aligned} n \ 2 \ I \ I &\rightarrow (2 \dots (2 (2 \ I)) \dots) \ I \\ &\rightarrow (2 \dots (2 (\lambda y. I (I \ y))) \dots) \ I \\ &\rightarrow (2 \dots (\lambda y. (\lambda y. I (I \ y)) (\lambda y. I (I \ y)) \ y) \dots) \ I \end{aligned}$$

In Haskell or SML the reduction of  $n \ 2 \ I \ I$  is exponential in  $n$  (while innermost reduction is obviously linear).

## Call by need is not optimal

We need to reduce under lambdas:

$$\mathbf{n} = \lambda xy.(x (x \dots (x y)))$$

$$\mathbf{2} = \lambda xy.(x (x y))$$

$$\mathbf{I} = \lambda x.x$$

$$\begin{aligned} n \mathbf{2} \mathbf{I} \mathbf{I} &\rightarrow (2 \dots (2 (2 \mathbf{I})) \dots) \mathbf{I} \\ &\rightarrow (2 \dots (2 (\lambda y. \mathbf{I}(\mathbf{I} y))) \dots) \mathbf{I} \\ &\rightarrow (2 \dots (\lambda y. (\lambda y. \mathbf{I}(\mathbf{I} y)))(\lambda y. \mathbf{I}(\mathbf{I} y)) y) \dots) \mathbf{I} \end{aligned}$$

In Haskell or SML the reduction of  $n \mathbf{2} \mathbf{I} \mathbf{I}$  is exponential in  $n$  (while innermost reduction is obviously linear).

# Innermost reduction of needed redexes is not optimal

$$\Delta = \lambda x.(x x) \quad M = \lambda x.(x I) \lambda y.(\Delta(y z))$$

# Virtual redexes and paths

- 4 The Cost of Optimal Sharing
  - A Typed setting
  - Eta expansion
  - A complexity bound

# Typed rules

the type of fans may only *decrease* during the reduction

# Typed rules

the type of fans may only *decrease* during the reduction

# Eta expansion

1  $\eta_o(x) = x$

2  $\eta_{\alpha_1 \rightarrow \dots \rightarrow \alpha_n \rightarrow o}(x) = \lambda y_1 : \alpha_1. \dots \lambda y_n : \alpha_n. (x \eta_{\alpha_1}(y_1) \dots \eta_{\alpha_n}(y_n))$

(a)  $\eta$ -expansion;

(b)  $\eta_{(o \rightarrow o) \rightarrow o \rightarrow o}(x)$

# Duplication of eta-expanded variables

Fan propagation stops on atomic types

# Duplication of eta-expanded variables

Fan propagation stops on atomic types

# Example: duplication of $\eta_{(o \rightarrow o) \rightarrow o \rightarrow o}(x)$

## Linear family reduction

### Optimal root:

For any subterm  $\lambda x : \sigma.P$  of  $M$ :

$$(*) \quad \lambda x : \sigma.P \rightarrow \lambda x'.(\lambda x.P \eta_{\sigma}(x'))$$

Let  $or(M)$  be the result of the transformation, and  $\Delta(M)$  be Lamping's normal form after firing all redexes of type  $(*)$ .

The number of  $\beta$ -redexes in the normalization of  $\Delta(M)$  is *linear* in its size!

## Linear family reduction

### Optimal root:

For any subterm  $\lambda x : \sigma.P$  of  $M$ :

$$(*) \quad \lambda x : \sigma.P \rightarrow \lambda x'.(\lambda x.P \eta_{\sigma}(x'))$$

Let  $or(M)$  be the result of the transformation, and  $\Delta(M)$  be Lamping's normal form after firing all redexes of type  $(*)$ .

The number of  $\beta$ -redexes in the normalization of  $\Delta(M)$  is *linear* in its size!

# The size of $\Delta(M)$

Let  $n(x)$  be the multiplicity of  $x$  in  $M$ .

## Theorem

*The number  $f$  of families of  $or(M)$  is less than*

$$2 * (|M| + \sum_{x \in M} n(x) * |\sigma(x)|)$$

*or also, by trivial simplifications*

$$2 * |M| * (\max_{\sigma} + 1)$$

# The cost of optimal sharing

## Corollary

*The cost of optimal  $\beta$ -reduction is not elementary recursive*

Hint: A generic non-elementary function can be simulated by a “small” simply typed term, and reduced in a linear number of optimally shared redexes.

**Not a negative result for Lamping’s technique!** Extremely expensive because extremely powerful.

The number of families *is not* a good measure of the intrinsic complexity of  $\lambda$ -terms.

# The cost of optimal sharing

## Corollary

*The cost of optimal  $\beta$ -reduction is not elementary recursive*

Hint: A generic non-elementary function can be simulated by a “small” simply typed term, and reduced in a linear number of optimally shared redexes.

**Not a negative result for Lamping’s technique!** Extremely expensive because extremely powerful.

The number of families *is not* a good measure of the intrinsic complexity of  $\lambda$ -terms.
